Fall 2010

DEI

http://dss.princeton.edu/training/

Panel data (also known as longitudinal or cross-sectional time-series data) is a dataset in which the behavior of entities are observed across time.

These entities could be states, companies, individuals, countries, etc.

Panel data looks like this

country	year	Y	X1	X2	Х3
1	2000	6.0	7.8	5.8	1.3
1	2001	4.6	0.6	7.9	7.8
1	2002	9.4	2.1	5.4	1.1
2	2000	9.1	1.3	6.7	4.1
2	2001	8.3	0.9	6.6	5.0
2	2002	0.6	9.8	0.4	7.2
3	2000	9.1	0.2	2.6	6.4
3	2001	4.8	5.9	3.2	6.4
3	2002	9.1	5.2	6.9	2.1

For a brief introduction on the theory behind panel data analysis please see the following document: http://dss.princeton.edu/training/Panel101.pdf

The contents of this document rely heavily on the document: "Panel Data Econometrics in R: the plm package" http://cran.r-project.org/web/packages/plm/vignettes/plm.pdf and notes from the ICPSR's Summer Program in Quantitative Methods of Social Research (summer 2010)

Exploring panel data

```
library(foreign)
Panel <- read.dta("http://dss.princeton.edu/training/Panel101.dta")</pre>
coplot(y ~ year|country, type="1", data=Panel) # Lines
coplot(y ~ year|country, type="b", data=Panel) # Points and lines
# Bars at top indicates corresponding graph (i.e. countries)
                                                                            Given : country
from left to right starting on the bottom row
(Muenchen/Hilbe:355)
                                                       1990 1992 1994 1996 1998
                                                                                          1990 1992 1994 1996 1998
                                                                        1990 1992 1994 1996 1998
```

Exploring panel data

```
library(foreign)
Panel <- read.dta("http://dss.princeton.edu/training/Panel101.dta")</pre>
library(car)
scatterplot(y~year|country, boxplots=FALSE, smooth=TRUE, reg.line=FALSE, data=Panel)
                                         country

    A

                                          \triangleB
                                          + C
                                          × D
                                          ♦ E
                                          \nabla F
                                          🗵 G
                                                ×
                                     5e+09
                                     0e+00
                                 >
                                     -5e+09
                                         1990
                                                     1992
                                                                 1994
                                                                              1996
                                                                                          1998

FIXED-EFFECTS MODEL

(Covariance Model, Within Estimator, Individual Dummy Variable Model, Least Squares Dummy Variable Model)

Fixed effects: Heterogeneity across countries (or entities)

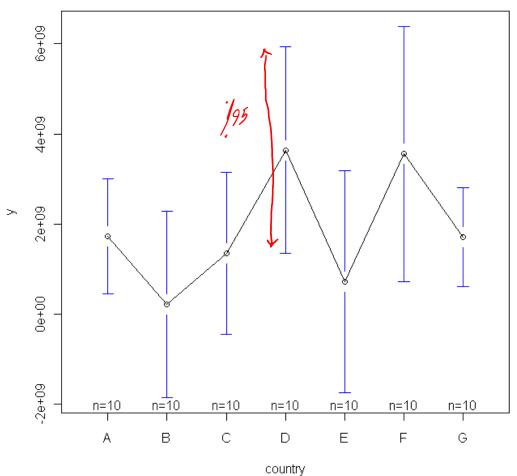

```
library(foreign)
Panel <- read.dta("http://dss.princeton.edu/training/Panel101.dta")
library(gplots)
plotmeans(y ~ country, main="Heterogeineity across countries", data=Panel)</pre>
```

plotmeans draw a 95%
confidence interval
around the means

detach("package:gplots")

Remove package 'gplots'
from the workspace

Heterogeineity across countries

Fixed effects: Heterogeneity across years

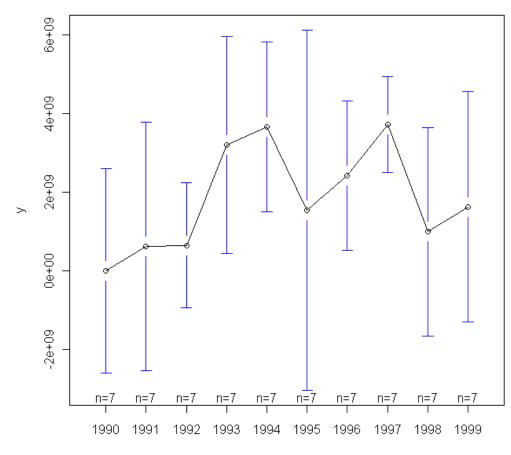

```
library(foreign)
Panel <- read.dta("http://dss.princeton.edu/training/Panel101.dta")
library(gplots)
plotmeans(y ~ year, main="Heterogeineity across years", data=Panel)</pre>
```

plotmeans draw a 95%
confidence interval
around the means

detach("package:gplots")

Remove package 'gplots'
from the workspace

Heterogeineity across years

```

For the theory behind fixed effects, please see http://dss.princeton.edu/training/Panel101.pdf

Least squares dummy variable model

- > yhat <- fixed.dum\$fitted</pre>
- > library(car)
- > scatterplot(yhat~Panel\$x1|Panel\$country, boxplots=FALSE, xlab="x1", ylab="yhat", smooth=FALSE)
- > abline(lm(Panel\$y~Panel\$x1),lwd=3, col="red")

Comparing OLS vs LSDV model

Each component of the factor variable (country) is absorbing the effects particular to each country. Predictor x1 was not significant in the OLS model, once controlling for differences across countries, x1 became significant in the OLS_DUM (i.e. LSDV model).

```
> library(apsrtable)
> apsrtable(ols,fixed.dum, model.names = c("OLS", "OLS DUM"))
                                                                                            # Displays a table in Latex form
                                   \begin{table}[!ht]
                                   \caption{}
                                   \label{}
                                   \begin{tabular}{ 1 D{.}{.}{2}D{.}{.}{2} }
                                     & \multicolumn{ 1 \}{ c \}{ OLS \} & \multicolumn{ 1 \}{ c \}{ OLS DUM \} \\
                                   \hline
                                                                                           11
                                                     & OLS
                                                                         & OLS DUM
                                                                                           11

summary(random.set)

FIXED OR RANDOM?

To decide between fixed or random effects you can run a Hausman test where the null hypothesis is that the preferred model is random effects vs. the alternative the fixed effects (see Green, 2008, chapter 9). It basically tests whether the unique errors (u_i) are correlated with the regressors, the null hypothesis is they are not.

Hausman Test

data: y ~ x1
chisq = 3.674, df = 1, p-value = 0.05527
alternative hypothesis: one model is inconsistent

A value 0.05 then use fixed effects

A value 0.05 then use fixed effects

A value 0.05 then use fixed effects

OTHER TESTS/ DIAGNOSTICS

Testing for time-fixed effects

```
> librarv(plm)
> fixed <- plm(y ~ x1, data=Panel, index=c("country", "year"),</pre>
model="within")
> fixed.time <- plm(y ~ x1 + factor(year), data=Panel, index=c("country",</pre>
"year"), model="within")
> summary(fixed.time)
Oneway (individual) effect Within Model

> # Breusch-Pagan Lagrange Multiplier for random effects. Null is no panel effect (i.e. OLS better).
```

The LM test helps you decide between a random effects regression and a simple OLS regression.

The null hypothesis in the LM test is that variances across entities is zero. This is, no significant difference across units (i.e. no panel effect). (http://dss.princeton.edu/training/Panel101.pdf)

```
> plmtest(pool, type=c("bp"))
              Lagrange Multiplier Test - (Breusch-Pagan)
      data: y \sim x1
      chisq = 2.6692, df = 1, p-value = 0.1023
      alternative hypothesis: significant effects
```

Here we failed to reject the null and conclude that random effects is not appropriate. This is, no evidence of significant differences across countries, therefore you can run a simple OLS regression.

Testing for cross-sectional dependence/contemporaneous correlation: using Breusch-Pagan LM test of independence and Pasaran CD test

According to Baltagi, cross-sectional dependence is a problem in macro panels with long time series. This is not much of a problem in micro panels (few years and large number of cases).

The null hypothesis in the B-P/LM and Pasaran CD tests of independence is that residuals across entities are not correlated. B-P/LM and Pasaran CD (cross-sectional dependence) tests are used to test whether the residuals are correlated across entities*. Cross-sectional dependence can lead to bias in tests results (also called contemporaneous correlation).

Testing for serial correlation

Serial correlation tests apply to macro panels with long time series. Not a problem in micro panels (with very few years). The null is that there is not serial correlation.

Testing for unit roots/stationarity

The Dickey-Fuller test to check for stochastic trends. The null hypothesis is that the series has a unit root (i.e. non-stationary). If unit root is present you can take the first difference of the variable.

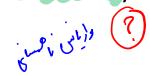

```
> Panel.set <- plm.data(Panel, index = c("country", "year"))
> library(tseries)
> adf.test(Panel.set$y, k=2)
         Augmented Dickey-Fuller Test

data: Panel.set$y
Dickey-Fuller = -3.9051, Lag order = 2, p-value = 0.01910
alternative hypothesis: stationary
```

If p-value < 0.05 then no unit roots present.

Testing for heteroskedasticity

The null hypothesis for the Breusch-Pagan test is homoskedasticity.

If hetersokedaticity is detected you can use robust covariance matrix to account for it. See the following pages.

Controlling for heteroskedasticity: Robust covariance matrix estimation (Sandwich estimator)

The --vcovHC- function estimates three heteroskedasticity-consistent covariance estimators:

- "whitel" for general heteroskedasticity but no serial correlation. Recommended for random effects.
- "white2" is "white1" restricted to a common variance within groups. Recommended for random effects.
- "arellano" both heteroskedasticity and serial correlation. Recommended for fixed effects.

The following options apply*:

- HCO heteroskedasticity consistent. The default.
- HC1, HC2, HC3 Recommended for small samples. HC3 gives less weight to influential observations.
- HC4 small samples with influential observations
- HAC heteroskedasticity and autocorrelation consistent (type ?vcovHAC for more details)

See the following pages for examples
